

How species are treated in Veg-X

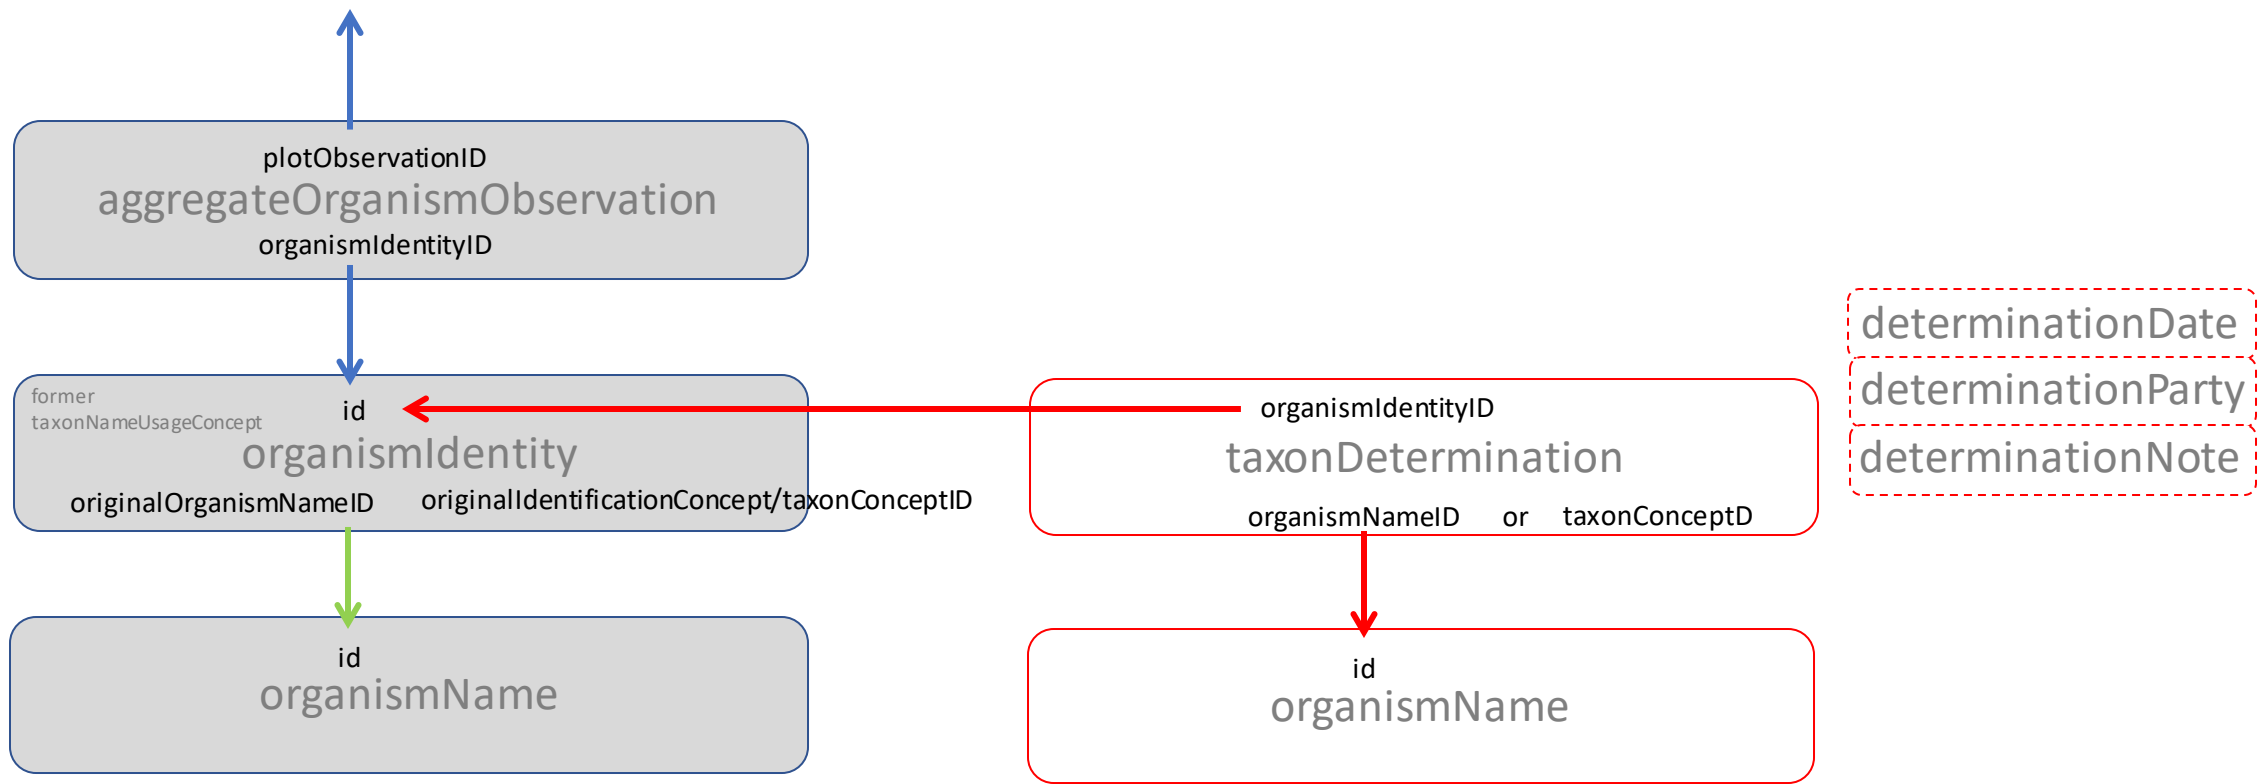

Each species record (= for example an `aggregateOrganismObservation`) links to an element made for specifying the 'identity' of the species (= `organismIdentity`)

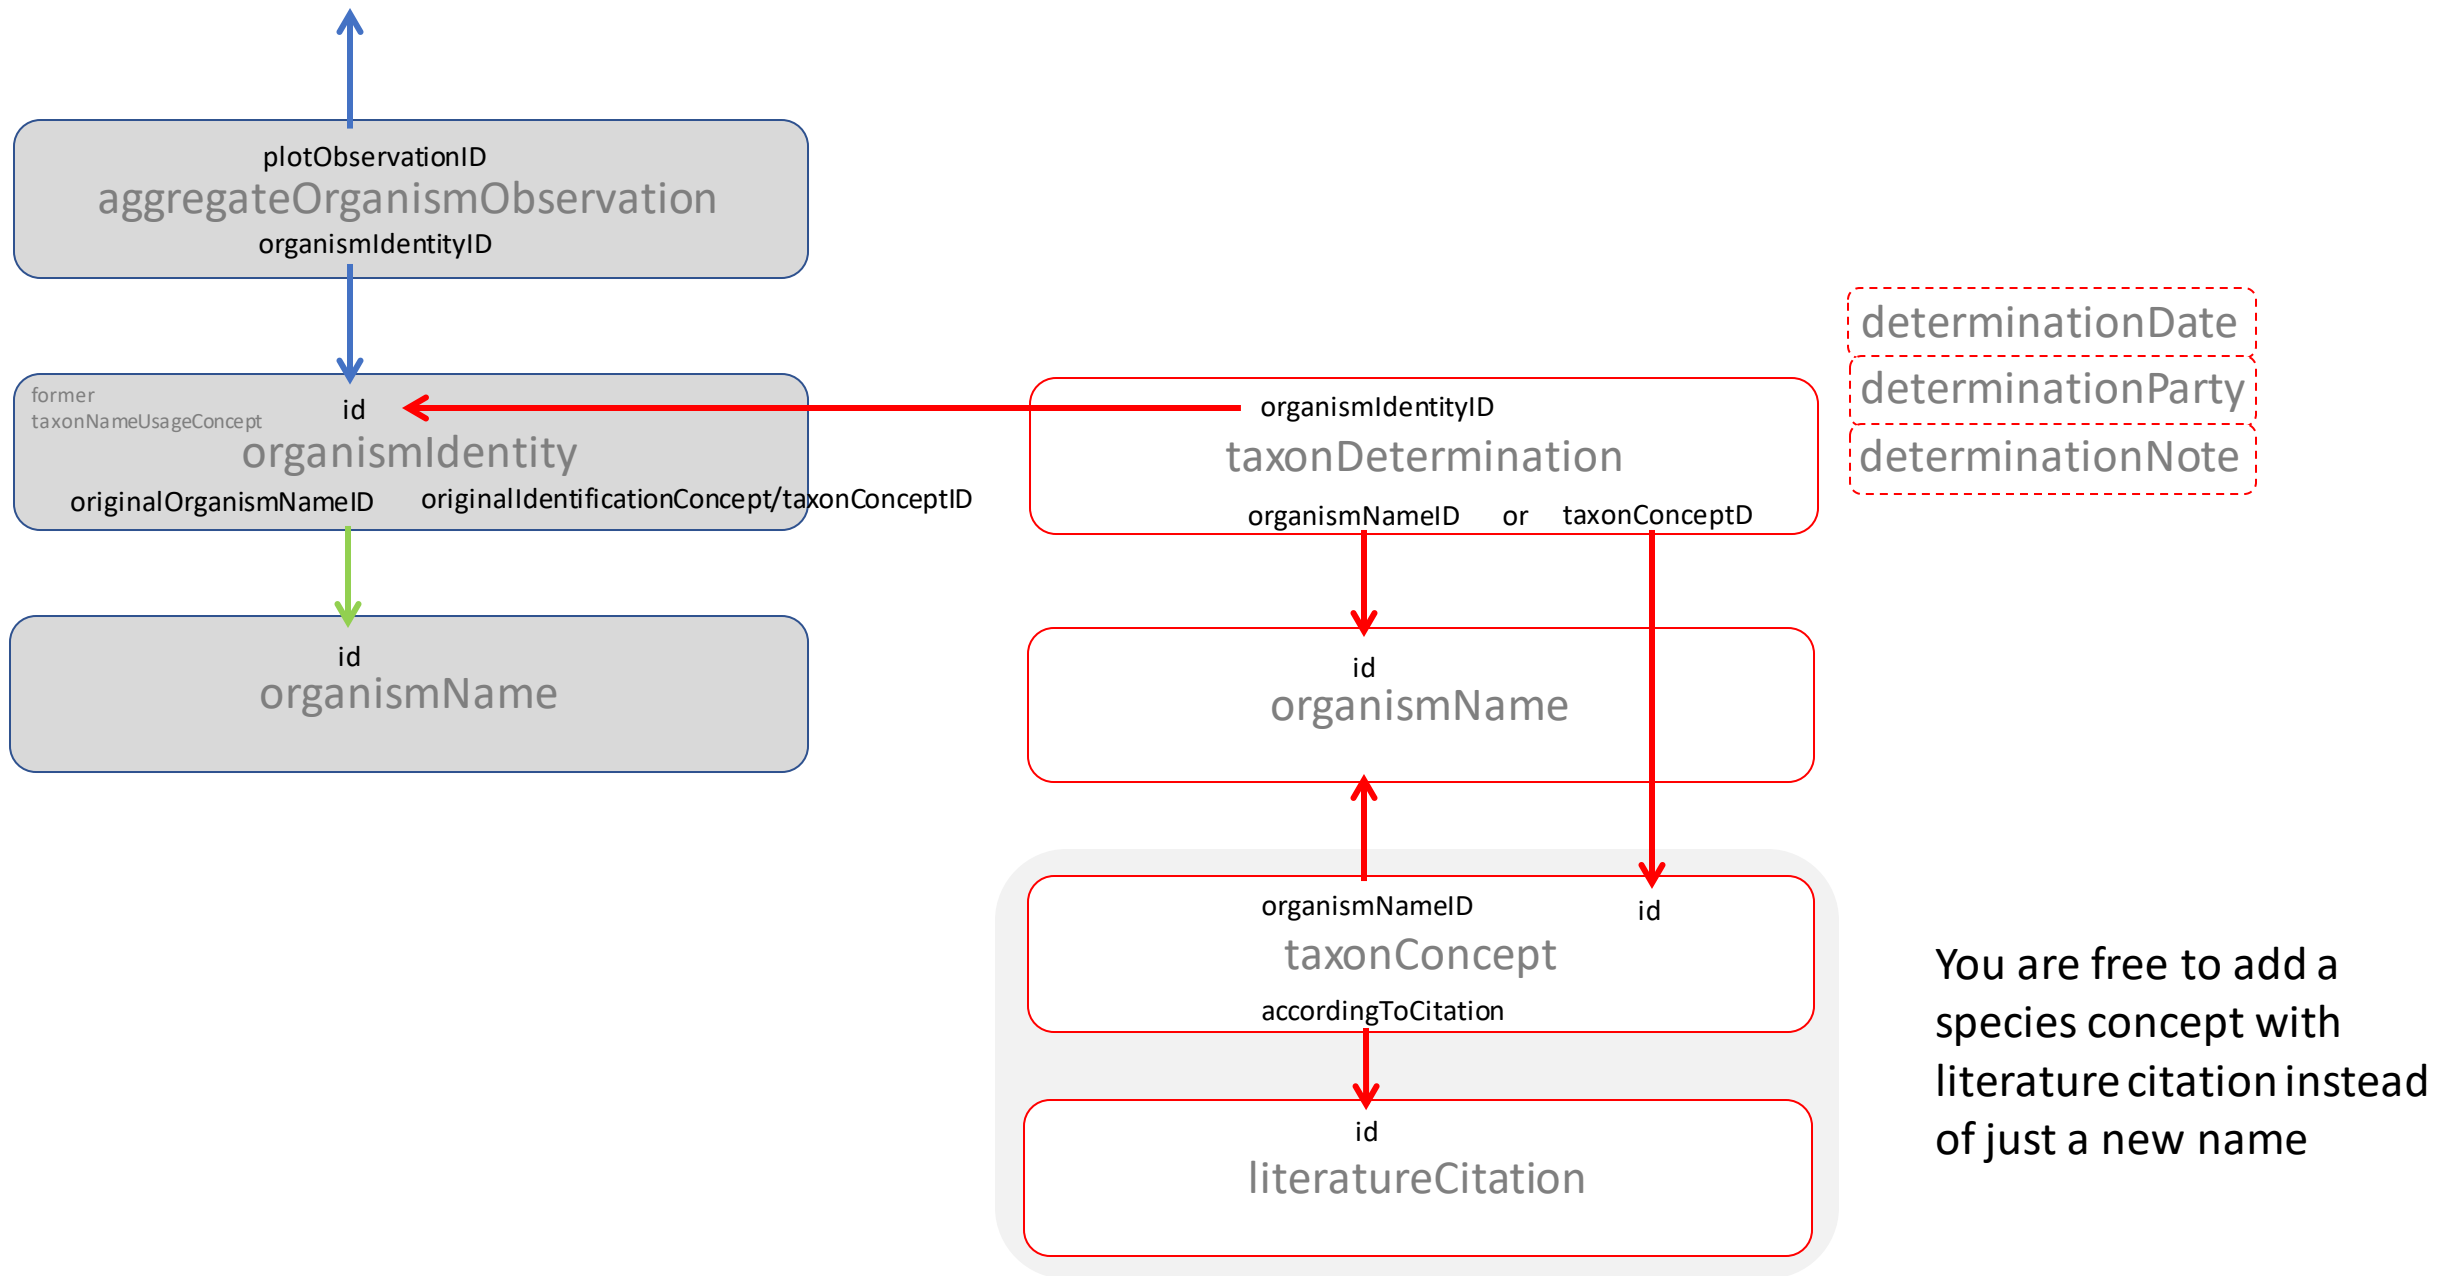

There is ideally an original name attached to this identity (the name used by the original author). The name can include authority. Apart from the name itself there is an attribute stating if it is a scientific name or not

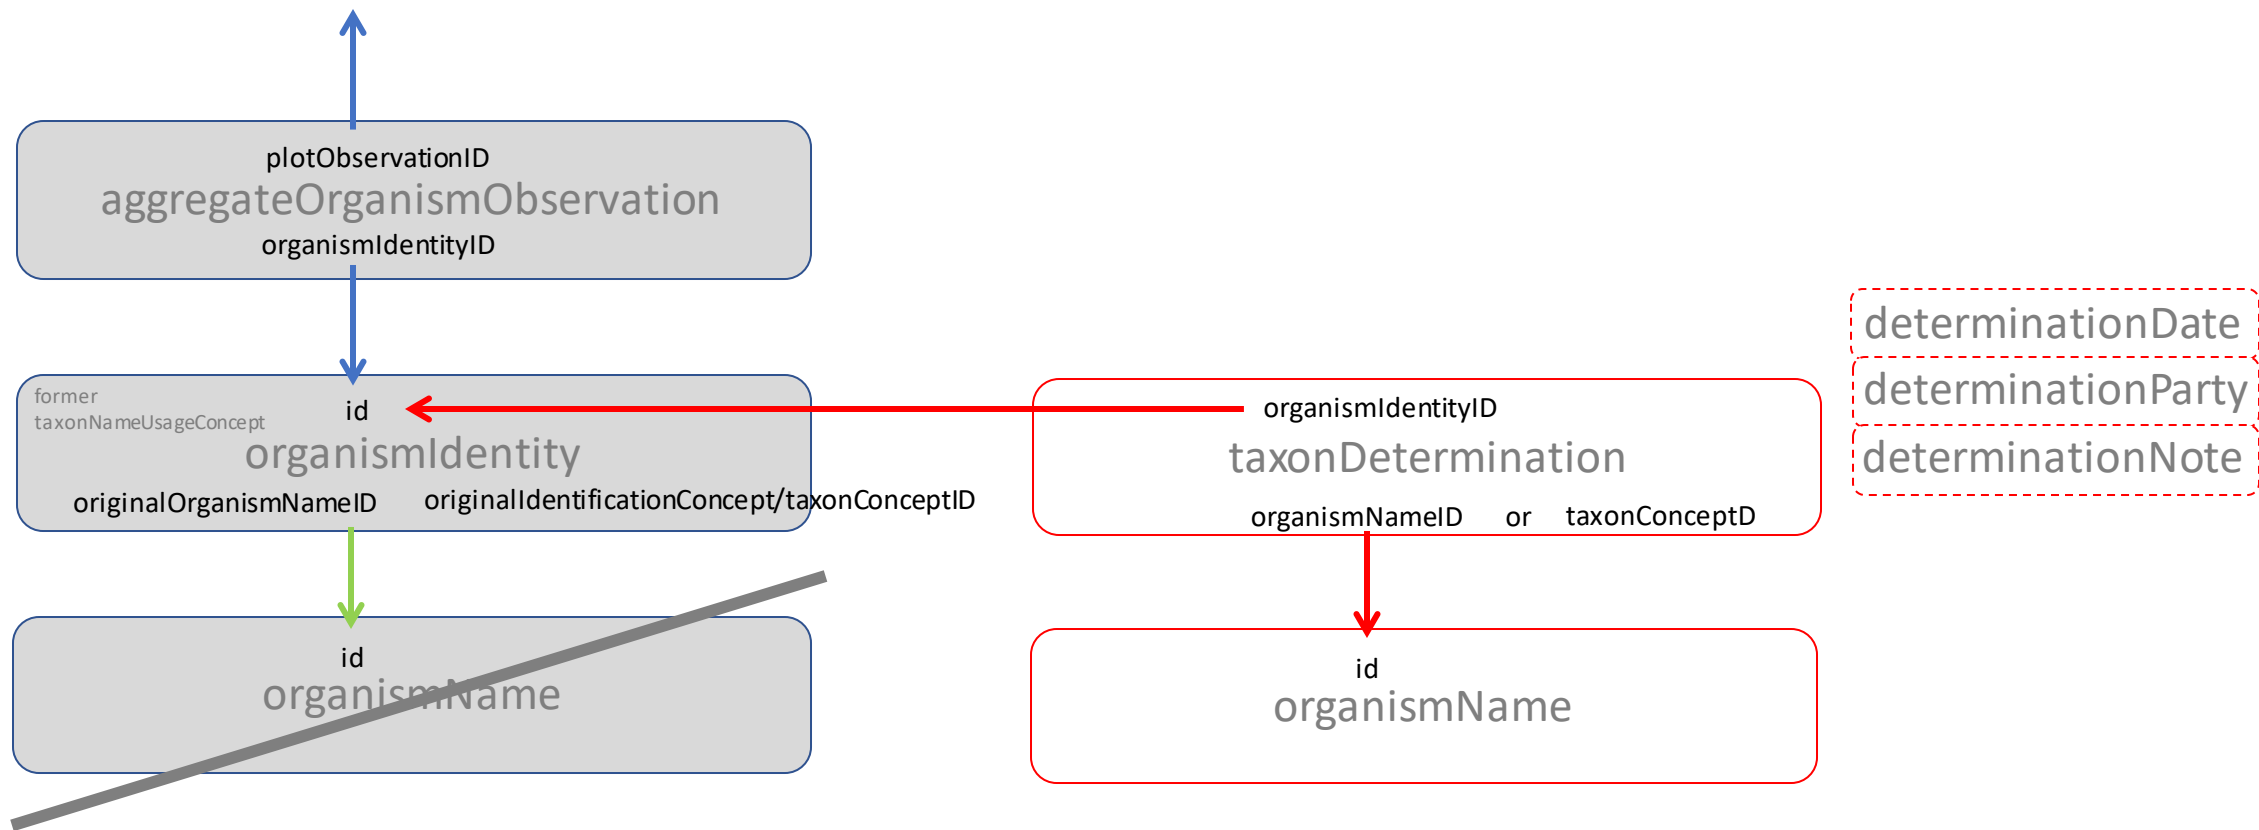

In some cases there is more information about which plant the original author had in mind when he wrote down the species name. In these cases a "taxon concept" can be added and linked to a literature citation. The latter can be a taxonomic reference list if this list provides information on the species concept, e.g. an identification key used. The list alone is not a concept if there is no such information attached to it.

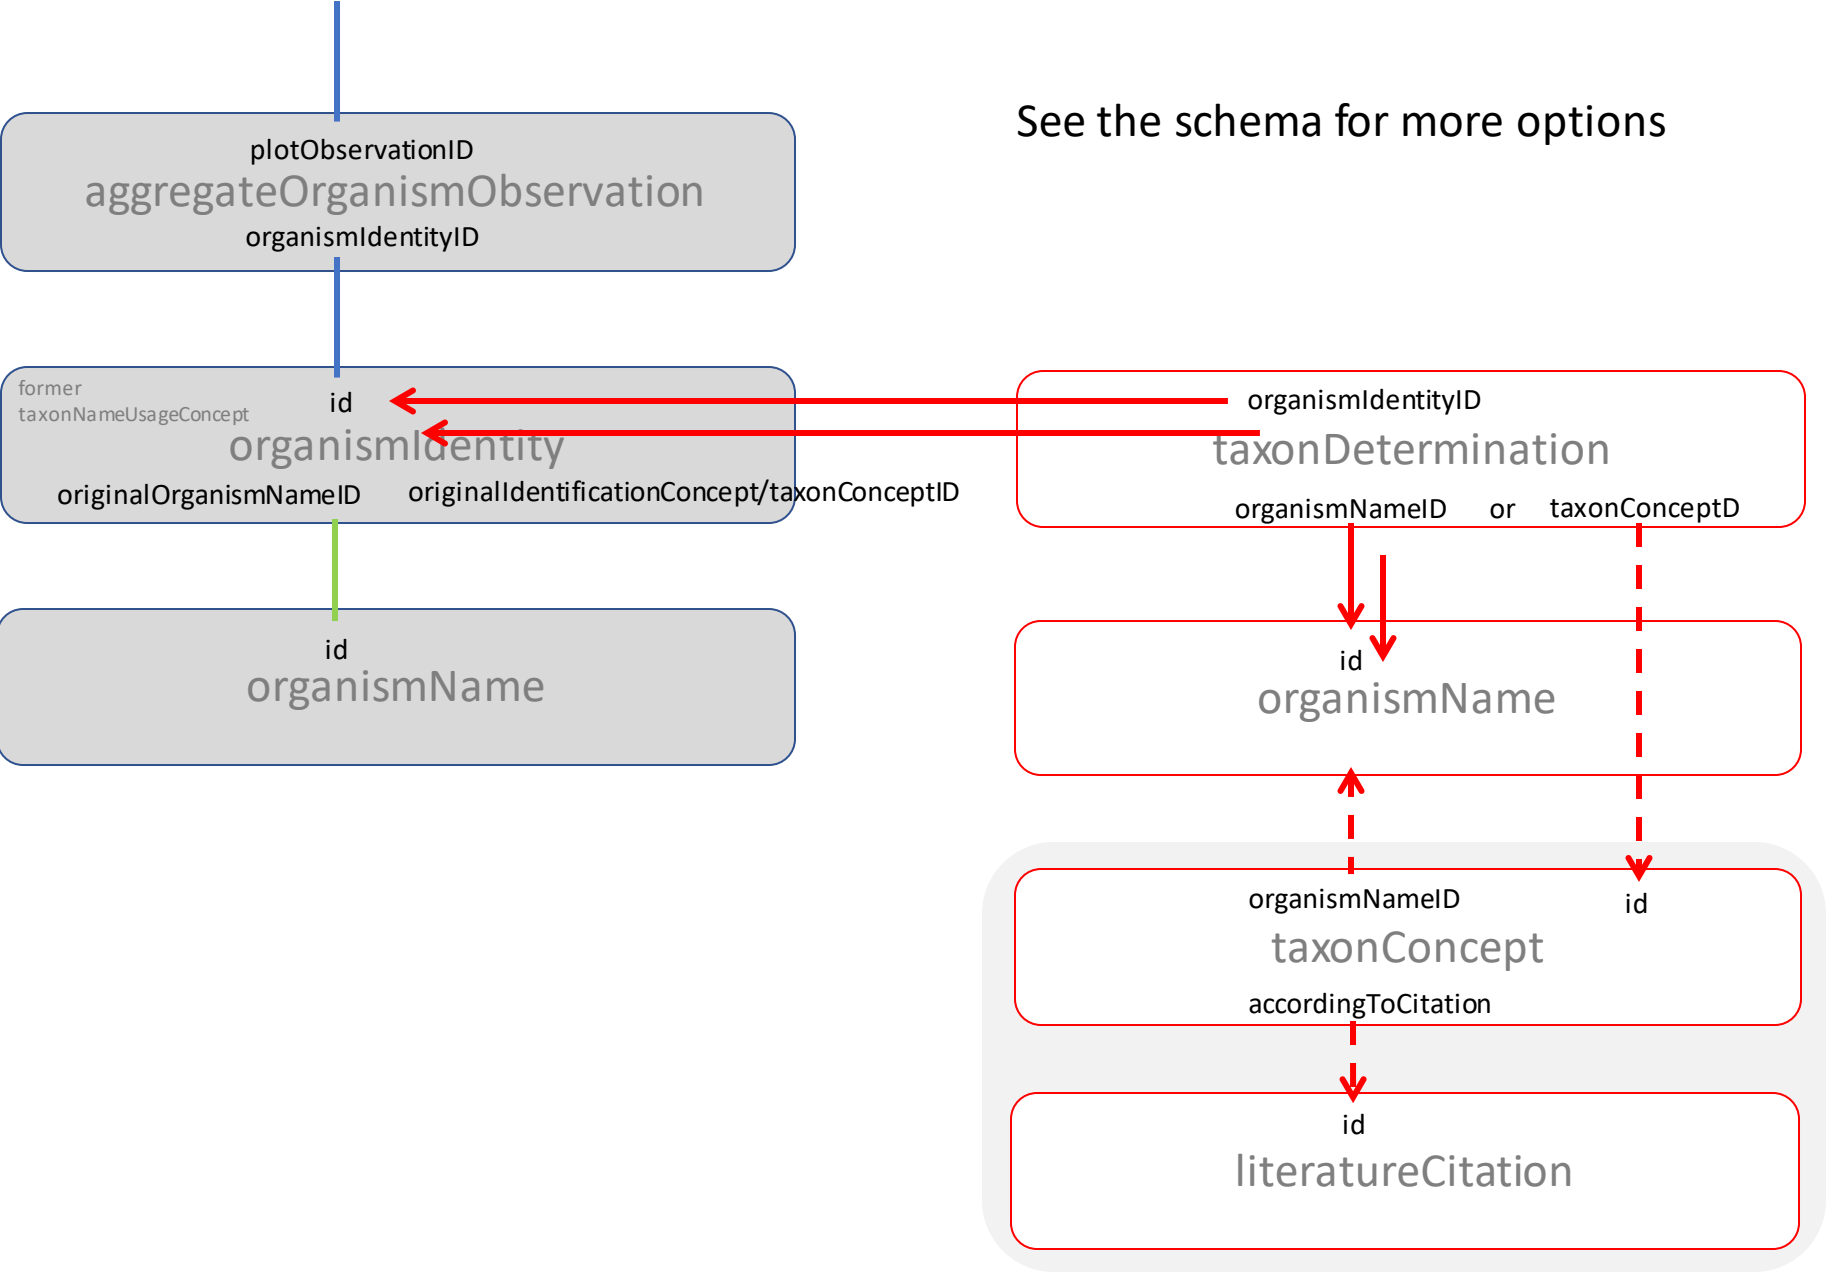

If a plant's identity is interpreted in a different way at some point in time, or if a new name is given by taxonomists, or if a standard list needs to be applied, or if a non-scientific name needs to be assigned, one or more taxon determinations can be added. In its most simple form it has only a species name attached to it but it can be useful to add an author and a date so the assignment can be traced back.

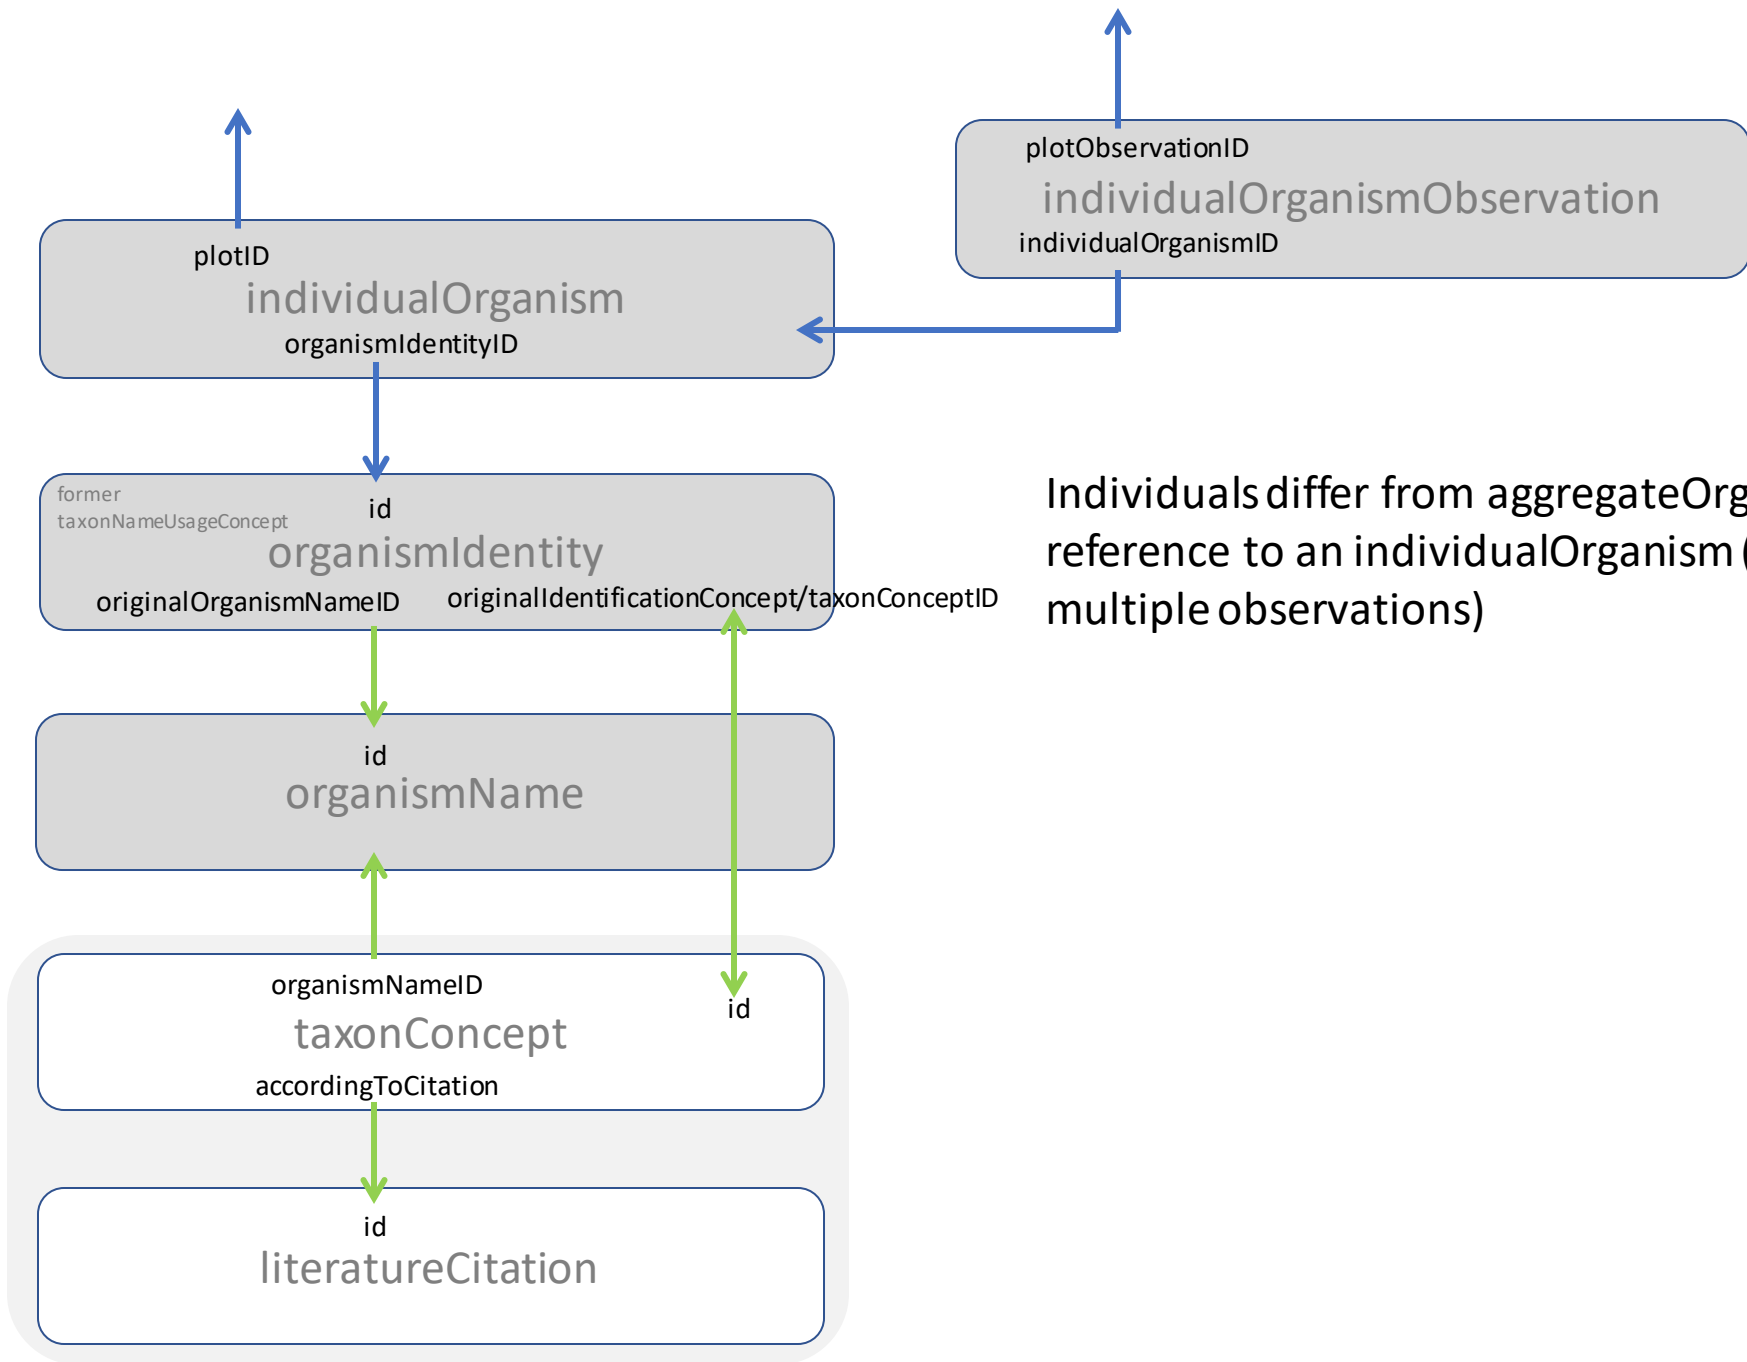

If the only available name is actually already an interpretation rather than the original name, a taxon determination can be added to make this clear.

See the schema for more options

Individuals differ from aggregateOrganisms in that they have a reference to an individualOrganism (which can be related to multiple observations)
